

Skim **Chapter 2** of the *Practical SQL* textbook and take brief notes on:

- How to create a **database** in PostgreSQL.

Use the command “create database” followed by the name you want to give it. Example: create database analysis;

- How to create a **table** (basic syntax and examples of data types).

The two keywords are **create** and **table**. Using the command “create table teachers” will create a table named teachers. Following that command with an open parenthesis and a comma-separated list will create columns for that table.

Example create table teacher (2 id 12345, 3 *firstname Nicole*(25), *lastname Hamrick*(50), school CSI(50) ; and so on. The parenthesis after *firstname*, *lastname*, and *school* specifies the maximum length of characters.

- Why semicolons are important in SQL.

Semicolons at the end of a command tell the system that it is the end of the command. Sometimes the commands will follow through without the semi colon, but not always.

- At least **two** examples of data types you might use in a table.

If the database were used for a college class, student ID numbers and student names are two examples of data types that you may find in a table.
